Using Offset Fetch Next for Paging in SQL server

- SQL server contains the offset & Next operators to implement paging. The offset operator offsets the next K number of search results from beginning, where the fetch Next operator fetches the Next N Results where K & N are integers.

The syntax of OFFSET NEXT as follows:

```
SELECT *
FROM Table_Name
ORDER by column_Names
OFFSET Number_of_Rows_to_skip Rows
FETCH NEXT Number_of_Rows_to_fetch Rows only
```

It is important to mention here that you have to use ORDER By clause with OFFSET FETCH NEXT clauses.

example of OFFSET FETCH NEXT where we will order the data by the id column of the cars table, skip the first 20 rows, & fetch the next 10 rows.

```
Use showroom
SELECT * from cars
ORDER by id
offset 20 rows
Fetch Next 10 Rows only
```

- the output of the script below, you will see records with id value of 21 to 30 since we skipped the first 20 records & fetched the next 10.

Using Offset Fetch NeXT W/ Stored Procedure

If you are Implementing Paging In a Front end application such as website or desktop application, You will typically send Page number & Page size values to the server via Stored procedure. Depending Upon the Value of the Page number & page size, the stored procedure will return the correct set of rows.

Continued...

This stored Procedure retrieves records using Paging

STORED Procedure EXAMPLE

```
Use ShowRoom
  Go
CREATE PROC SpGetRecordsByPageAndsize
@Page int,
@Size int
As
BEGIN
  SELECT * FROM CARS
  ORDER By id
  OFFSET (@Page -1) * size Rows
  FETCH Next @Size Rows only
END
```

for instance, if the Page number is 2, & Size is 20, the offset will be (2 - 1) * 20 = 20
